Demonstration examples of work

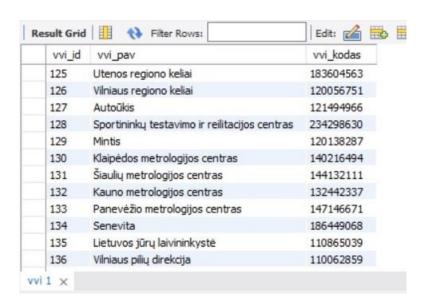

All examples are non-final and only demonstration for confidentiality reasons also only few examples of many, most of these examples are first attempts just to show my skills diversity and what can i do by attempting for a first time, that is why most likely I will know "why" and "what" to do.

Use of the database

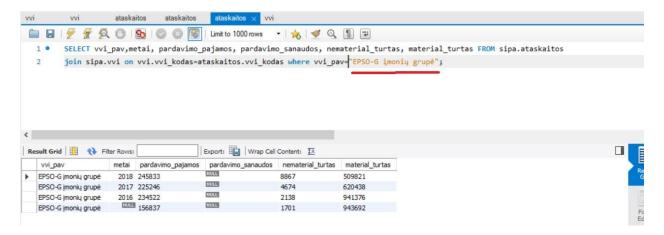

The database structure created and the merged connections are linked using MySQL Workbench, however this is not the final version, it is just the first version presented as an example.

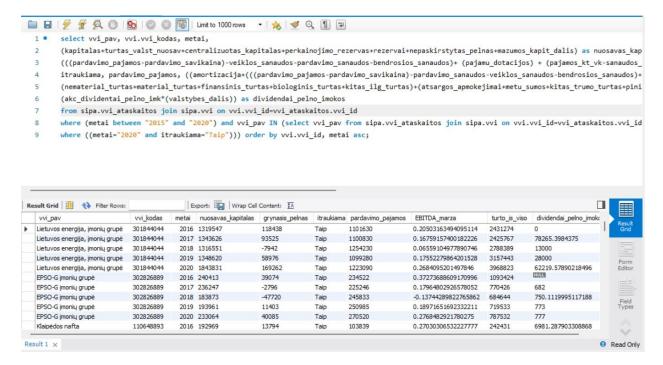

The financial and related data of the SOEs are extracted from the aggregated excel documents and placed in a database table containing all SOEs. The data of the SOE are connected to table through vvi_id, because there are problems when using the company name or code as an identifier - the company name may change, the company code also occurs that the company code is given to another company duo to the merge or other scenario.

One example of demonstration was the data for 2014-2018 and merged with the SOE table (aggregation by company code for demonstration). The query indicated the name of the parody company, year, sales of income and so on, according to the chosen company name.

Another example of an demonstration query that required certain data to be calculated as equity, EBITDA margin, for a certain period of the year, also these companies have to be operating today.

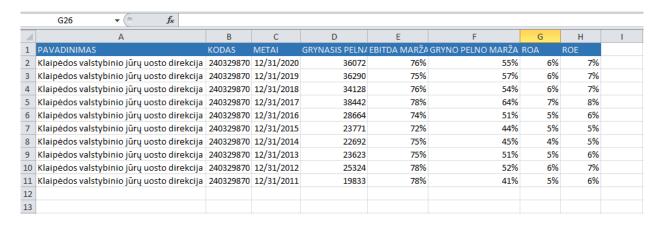

Using Excel with a database and its data

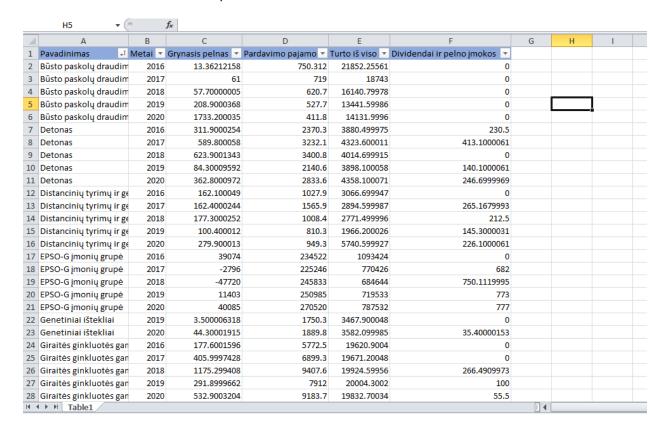

The demonstrative use of the database, in this case, goal was to extract the ROA data from the database and present it in excel format.

A demonstrative variant of one company, after extracting the data from the database, all the data are calculated using SQL code and extracted in excel format.

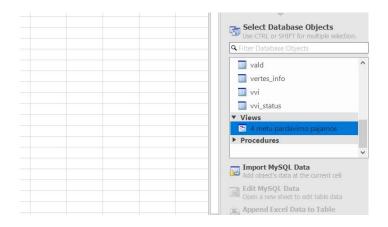

The last demonstrative example of how to extract some calculated data from a created database

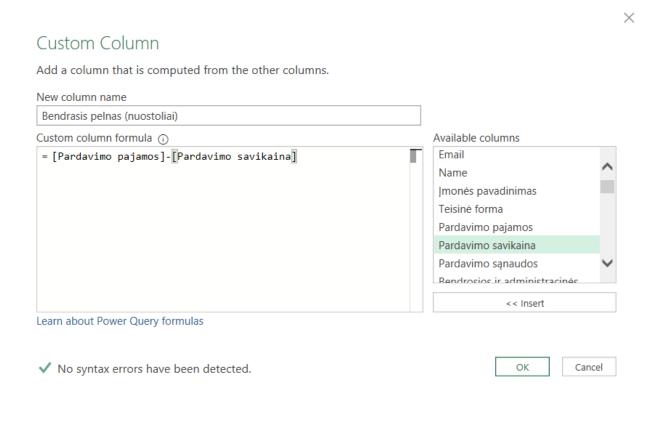

Another demonstrative example is connecting a database to excel. Views created (views - code is generated and saved as a template). The created "views" select the sales revenue for all the last 4 years specified in the SOE, then it is possible to extract that data into excel (or another program) and analyze it.

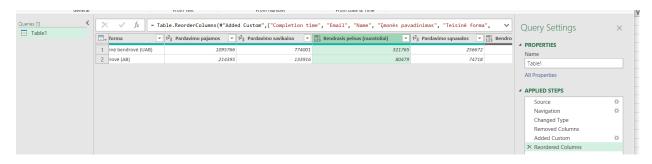

The results provided can be changed from "vvi_pav" to "Company Name" or some criteria can be added to extract the data. Instead of excel, you can connect another analytics tool like Power BI to create an interface to extract data.

The demonstration in Excel using Power Query, the data is sorted according to needs, I have added an additional table "Gross profit (loss)" for additional calculations.

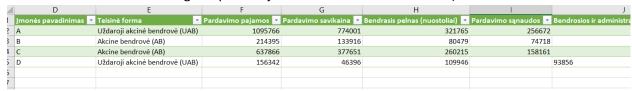

Then the sorted data can be taken to excel.

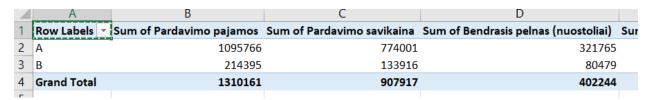

When new data is received, "refresh" is clicked and all data and calculations are updated (for example, "gross profit" I just created it to calculate now).

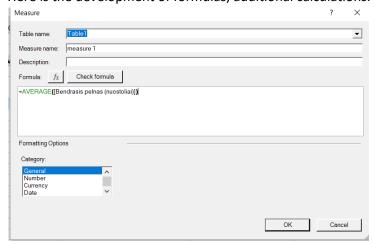

When creating aggregated documents using PivotTable or PowerPivot, clicking "refresh" immediately creates new data and calculates it.

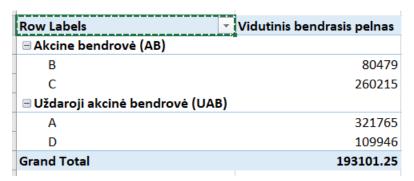

Row Labels - now the name of the company, but you can change what you want to aggregate - company name, legal form, year, etc.

After updating the data from the form to calculate everything that was desired before, it is possible to create the desired wording "Measure" yourself, I gave as an example "average gross profit" and then everything can be visualized.

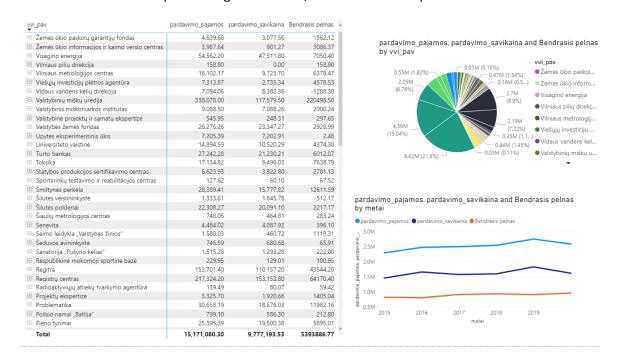

Here is the development of formulas, additional calculations.

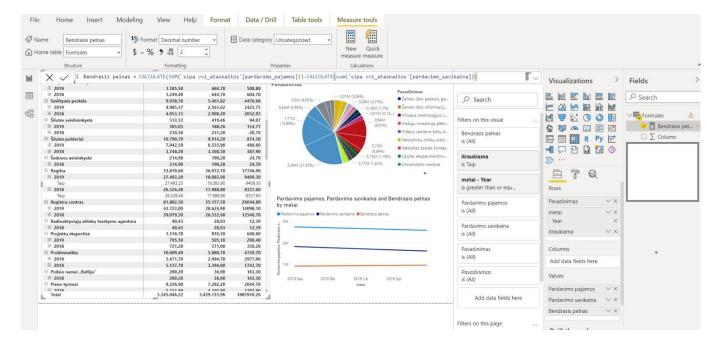

Using Power BI connected to created database

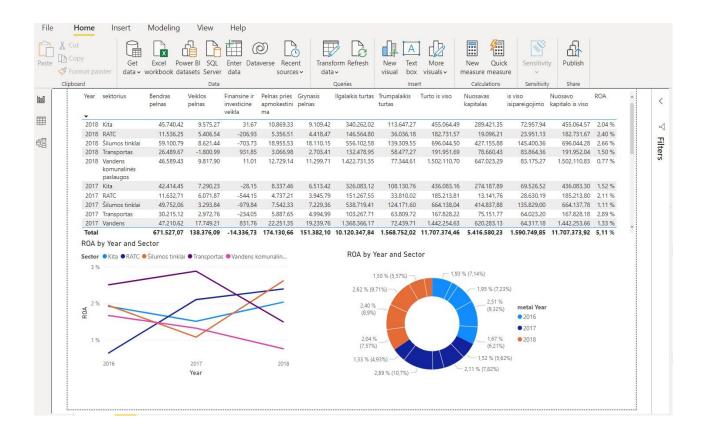

Demonstration of Power BI in a visually unfinished way by connecting the created database and performing calculations, in this case - total profit.

Demonstration of Power BI using filters, DAX formulas, and the like, as a test case.

The last demonstration option for connecting the database and calculating the data using DAX formulas, but this option, as before, is not visually finished; it is only a test demonstration version.

Using Excel VBA

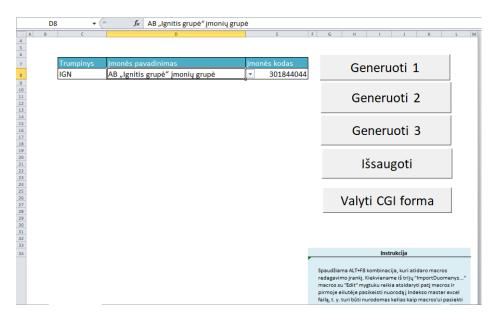

The excel file is created by assembling from an aggregated excel containing hundreds of companies, then extracting the required data using VBA, placing it in a plugin created in Wordpress and displaying the data on a website.

Another example of using excel VBA is to extract data from a particular excel documents then generate new document and save it to the desktop. (It is generated in three pieces of VBA code, because Excel allows only a certain number of line code, and a large amount of data is in these Excel documents, if you run all VBA code at once it will crash Excel).

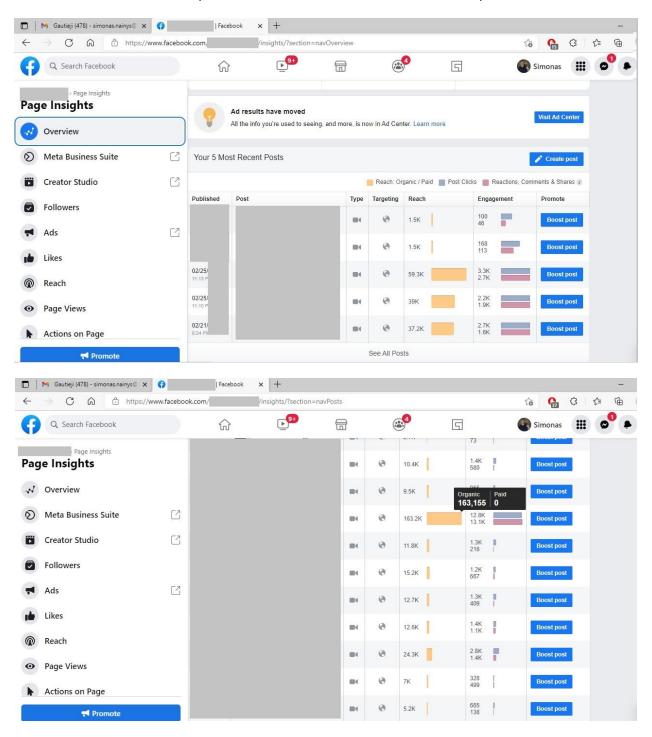

A form with hundreds of lines has been created, filled in and saved on the desktop.

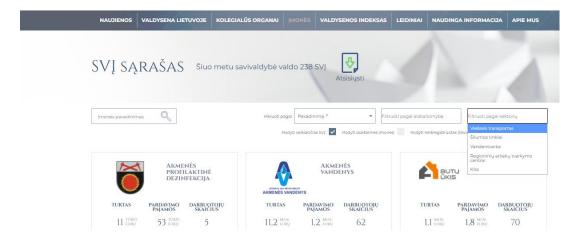

Use of digital marketing

Here is an example of a Facebook page Organic Reach test, showing the results, this page was created for a week only, some information is hidden for confidentiality as usual.

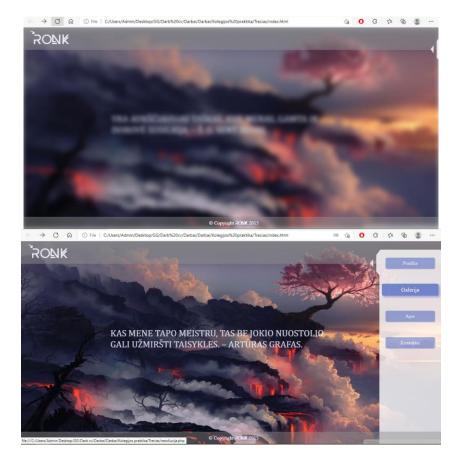

Website adjustment, creation and coding examples

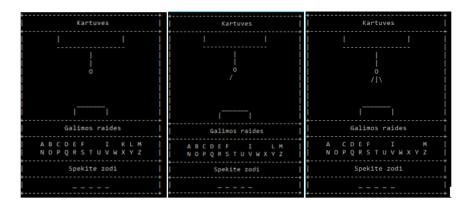

In this example, we see the editing of "php" code, where enterprise filtering has been adjusted and created and just one example of adjusting websites code and creation of first website.

Other example of website creation is my first ever website created in 2015; sidebar navigation sliding was created from scratch only using CSS, no JavaScript etc.

Creating "hanging" game with C++, of course there are many other examples and demonstrations where I use "Java", "Bootstrap", Software testing or other technologies, however it is not my main focus.

Use of graphic design

Here we can see created art exhibition poster as demonstration from zero, invitation to kid birthday or political stand display and bucket for Social Democratic Party of Lithuania, however it is not main focus, which is why I only put here few examples.
